**ABSTRACT:** In this article we study every subgroups is locally subnormal. We prove that if  $G$  be a torsion-free group in  $\mathcal{P}_2 \cap \mathcal{P}_n$ , for all  $1 \leq n \in \mathbb{N}$  and assume that for every homomorphic image  $\bar{G}$  of  $G$  has a non-trivial abelian normal subgroup, then  $G$  is soluble. We also prove that if  $G$  be a hyperabelian torsion-free group in  $\mathcal{P}_{2,n}$ , then  $G$  is nilpotent group.

**Keywords:** locally subnormal, hyperabelian, soluble, Engel group.

## INTRODUCTION

### Subnormal Subgroups:

A group  $H$  of the group  $G$  is said to be subnormal if  $H$  is a term of a finite series of  $G$ ; if there exists  $d \in \mathbb{N}$  and series of subgroups, such that

$$H = H_d \triangleleft H_{d-1} \triangleleft \dots \triangleleft H_0 = G$$

If  $H \triangleleft\triangleleft G$  then the defect of  $H$  in  $G$  is the shortest length of such a series: it will be denoted by  $d(H, G)$ . We shall say that a subgroup  $H$  of  $G$  is  $n$ -subnormal if  $H \triangleleft\triangleleft G$  and  $d(H, G) \leq n$ . We denote by  $\mathcal{P}_1$  the class of all groups which every subgroup  $H$  of  $G$  is subnormal.

### Normalize Condition:

A group  $G$  said to satisfy the normalizer condition if

$H \neq N_G(H)$  for all proper subgroups  $H$  of  $G$ . We denote by  $\mathcal{P}$  the class of all groups satisfying normalizer condition.

### Locally Subnormality

A class which is intermediate between  $\mathcal{P}_1$  and  $\mathcal{P}$  class of groups in which every subgroup is locally subnormal; where a subgroup  $H$  of a group  $G$  is called locally subnormal if

$H \triangleleft\triangleleft \langle H, X \rangle$  for all finite  $X \subset G$ . The class we denoted by  $\mathcal{P}_2$ .

### Isolator:

Let  $H$  be a subgroup of a group  $G$ . the isolator of  $H$  in  $G$  is the set

$$I_G(H) = \{x \in G : x^n \in H, \text{ for some } 1 \leq n \in \mathbb{N}\}$$

Let us denote by  $\mathcal{P}_n$  the class groups in which every soluble subgroups is soluble of derived length  $n$ , for each  $1 \leq n \in \mathbb{N}$

$\mathcal{P}_{2,n}$  class of groups in which every subgroup is locally subnormal; where a subgroup  $H$  of a group  $G$  is called locally subnormal if  $H \triangleleft\triangleleft G$  for all finite  $X \subset G$  and subnormal indices bounded  $n$ , where  $1 \leq n \in \mathbb{N}$ .

**Mainresults**

**Lemma 1.**

Let G be a group in  $\mathcal{P}_2$ . Then G is locally nilpotent.

**Proof.**

Let F be finitely generated subgroup of G. By hypothesis, for all  $x \in F$ ,  $\langle x \rangle$  is subnormal subgroup of F. F is a nilpotent group by 12.2.8(1). Thus G is locally nilpotent.

**Lemma 2.**

Let G be a hyperabelian torsion-free group in  $\mathcal{P}_2 \cap \mathcal{P}_n$ , for all  $1 \leq n \in \mathbb{N}$ . Then G is soluble.

**Proof.**

Suppose that G is not soluble. Since G is hyperabelian, then there exists non-soluble normal subgroup L of G such that  $L = \bigcup_{i \in \mathbb{N}} A_i$ , where  $A_i$  is soluble normal subgroups of G, for all  $i \in \mathbb{N}$  by (5) Lemma (3). But by hypothesis, for all  $i \in \mathbb{N}$ ,  $A_i$  is soluble of derived length n. Thus L is soluble. This is a contradiction.

**Theorem A .**

Let G be a torsion-free group in  $\mathcal{P}_2 \cap \mathcal{P}_n$ , for all  $1 \leq n \in \mathbb{N}$  and assume that for every homomorphic image  $\bar{G}$  of G has a non-trivial abelian normal subgroup. Then G is soluble.

**Proof.**

Suppose that G is not soluble. By hypothesis G has an abelian normal subgroup A of G.  $I_G(A)$  is an abelian normal subgroup of G by (1) Lemma (ii),(v)(3). If  $G = I_G(A)$ , then G is soluble by (1)(v) (3). Assume that  $G \neq I_G(A) = A_1$ .

$G/A_1$  is torsion-free. By hypothesis,  $G/A_1$  has an abelian group  $B_1/A_1$ . Also  $B_1$  is soluble. If  $I_G(B_1) = G$ , then G is soluble. Assume that  $A_2 = I_G(B_1) \neq G$ . Then  $G/A_2$  is torsion-free. Now assume that we have subgroups  $A_\lambda \neq G, A_\lambda \triangleleft G$  and  $G/A_\lambda$  is torsion-free,  $\alpha$  is ordinal number, for all  $\lambda \leq \alpha, \alpha > 1$ . If  $\alpha$  is limit ordinal,  $A_\alpha = \bigcup_{\lambda < \alpha} A_\lambda$ .

If  $\alpha$  is not limit ordinal, there exists  $\alpha - 1$  such that  $G/A_{\alpha-1}$  is torsion-free. Similar to the definition of  $A_\alpha/A_{\alpha-1}$  is defined in  $G/A_{\alpha-1}$  and  $G/A_{\alpha-1}$  is torsion-free. If it is continued in such a way that there exists a ordinal number  $\beta$  such that  $G = A_\beta, \{A_\alpha : \alpha \leq \beta\}$  is hyperabelian series of G. Thus G is soluble by Lemma 2.

**Lemma 3.**

Let G be a group in  $\mathcal{P}_2$ . Then G is an Engel group.

**Proof.**

For all  $x, y \in G$ , by hypothesis  $\langle x \rangle \triangleleft \triangleleft \langle x, y \rangle$ . Then there exists a n natural numbers such that  $[\langle x, y \rangle, n \langle x \rangle] \leq \langle x \rangle$

This implies that

$$[y, (n+1)x] = 1$$

Thus G is Engel group.

**Corollary**

Let G be a hyperabelian torsion-free group in  $\mathcal{P}_{2,n}$ . Then G is nilpotent group.

**Proof.**

G is soluble by Teorem A. For all

$$x, y \in G$$

$\langle x \rangle$  is subnormal in  $\langle x, y \rangle$  and  $\langle y \rangle$  is subnormal in  $\langle x, y \rangle$ . Since subnormal indices is n,  $[\langle x, y \rangle, n\langle x \rangle] \leq \langle x \rangle$  and  $[\langle x, y \rangle, n\langle y \rangle] \leq \langle y \rangle$ . This implies that  $[y, (n+1)x] = 1$  and  $[x, (n+1)y] = 1$ . Thus G is (n+1)-Engel group. G is nilpotent by Corollary in page 64(2).
